

A model of Hall reconnection

Leonid M. Mal'ys'kin*

Department of Astronomy & Astrophysics, University of Chicago, 5640 S. Ellis Ave., Chicago, IL 60637

(Dated: December 17, 2008)

The rate of quasi-stationary, two-dimensional magnetic reconnection is calculated in the framework of incompressible Hall magnetohydrodynamics (MHD), which includes the Hall and electron pressure terms in the Ohm's law. The Hall-MHD equations are solved in a local region across the reconnection electron layer, including only the upstream region and the layer center. In the case when the ion inertial length d_i is larger than the Sweet-Parker reconnection layer thickness, the dimensionless reconnection rate is found to be independent of the electrical resistivity and equal to d_i/L , where L is the scale length of the external magnetic field in the upstream region outside the electron layer, and the ion layer thickness is found to be d_i .

INTRODUCTION

Magnetic reconnection is a fundamental process of breaking and topological rearrangement of magnetic field lines in magnetized plasmas. Reconnection converts magnetic energy into kinetic and thermal energy and is believed to be responsible for many phenomena observed in the laboratory and cosmic plasmas [1, 2]. Because electrical resistivity is very low in hot plasmas, magnetic reconnection due to resistive dissipation of magnetic field is typically a very slow process [1, 2, 3]. Reconnection can become much faster in the case when resistivity is anomalously high due to local plasma instabilities [3, 4, 5]. Another possibility is fast reconnection made possible because of two-fluid plasma effects [1], which require a two-fluid magnetohydrodynamics (MHD) description of plasma. In the limit of zero electron-to-ion mass ratio, two-fluid MHD equations simplify and reduce to Hall-MHD equations. The later include the Hall and electron pressure terms in the Ohm's law, in addition to the resistivity term present in single-fluid MHD. Because of its relative simplicity, Hall-MHD description of plasma has been extensively used in numerical simulations of magnetic reconnection [6, 7, 8, 9]. However, to the best of our knowledge, a simple self-consistent analytical model of Hall reconnection, similar to the classical Sweet-Parker model of resistive reconnection, has not been constructed. In this paper we consider Hall-MHD equations and present a theoretical model of Hall reconnection. Full two-fluid calculations for magnetic reconnection will be considered elsewhere. The analytical derivations of this paper are similar to the derivations done by Mal'ys'kin, Linde & Kulsrud [5] for the case of resistive single-fluid MHD reconnection.

HALL-MHD EQUATIONS

For simplicity and brevity, we use physical units in which the speed of light c and four times π are replaced by

unity, $c = 1$ and $4\pi = 1$. To rewrite our equations in the CGS units, one needs to make the following substitutions: magnetic field $\mathbf{B} \rightarrow \mathbf{B}/\sqrt{4\pi}$, electric field $\mathbf{E} \rightarrow c\mathbf{E}/\sqrt{4\pi}$, electric current $\mathbf{j} \rightarrow \sqrt{4\pi}\mathbf{j}/c$, electrical resistivity $\eta \rightarrow \eta c^2/4\pi$, and the proton electric charge $e \rightarrow \sqrt{4\pi}e/c$.

We assume the plasma is non-relativistic, with both phase and physical velocities much smaller than the speed of light. We neglect electron inertia for the Hall-MHD description of plasma. The generalized Ohm's law is [10]

$$\mathbf{E} = -\mathbf{V} \times \mathbf{B} + \eta \mathbf{j} + \frac{m_i}{\rho e} \mathbf{j} \times \mathbf{B} - \frac{m_i}{\rho e} \nabla \cdot \mathbf{P}_e, \quad (1)$$

where m_i is the ion mass, ρ is the plasma density, $\mathbf{V}$ is the plasma velocity (equal to the ion velocity), $\mathbf{P}_e$ is the tensor of the electron pressure. The first two terms on the right-hand side of Eq. (1) are the single-fluid MHD terms, the third and fourth terms are the Hall and electron pressure terms. The equation of plasma motion is [10]

$$\rho \frac{\partial \mathbf{V}}{\partial t} + \rho (\mathbf{V} \cdot \nabla) \mathbf{V} = -\nabla \cdot \mathbf{P} + \mathbf{j} \times \mathbf{B}, \quad (2)$$

where $\mathbf{P}$ is the tensor of the total pressure (equal to the sum of the electron and ion pressure tensors), and we neglect plasma viscosity. Equation (2) appears exactly the same as in the case of single-fluid MHD. Note that $\nabla \cdot \mathbf{B} = 0$, and, for non-relativistic plasma, $\nabla \cdot \mathbf{j} = 0$.

We consider Hall magnetic reconnection in the classical two-dimensional Sweet-Parker-Petschek reconnection layer, shown in Fig. 1. The layer is in the x-y plane with the x- and y-axes being perpendicular to and along the layer respectively. All $\partial/\partial z$ derivatives are zero. The thickness of the reconnection layer is 2δ , which is defined as the thickness of the out-of-plane current (j_z) profile across the layer. Note that 2δ is approximately equal to the electron layer thickness, while the ion layer thickness 2Δ can be much larger. Velocity V_{in} is the plasma inflow velocity in the upstream region at point M , outside the electron layer. The magnetic field B_m at point M is in the y-direction. The out-of-plane field B_z is assumed to have a quadrupole structure (see Fig. 1), in agreement with nu-

FIG. 1: Geometrical configuration of the reconnection layer.

merical simulations and laboratory experiments of two-fluid reconnection [6, 7, 8, 9, 11, 12, 13, 14, 15, 16, 17] (a nearly uniform “guide” field component of B_z is taken to be zero). The reconnection layer is assumed to have a point symmetry with respect to its geometric center point O in Fig. 1 and reflection symmetries with respect to the axes x and y . Thus, the x -, y - and z -components of $\mathbf{V}$, $\mathbf{B}$ and $\mathbf{j}$ have the following simple symmetries: $V_x(\pm x, \mp y) = \pm V_x(x, y)$, $V_y(\pm x, \mp y) = \mp V_y(x, y)$, $V_z(\pm x, \mp y) = V_z(x, y)$, $B_x(\pm x, \mp y) = \mp B_x(x, y)$, $B_y(\pm x, \mp y) = \pm B_y(x, y)$, $B_z(\pm x, \mp y) = -B_z(x, y)$, $j_x(\pm x, \mp y) = \pm j_x(x, y)$, $j_y(\pm x, \mp y) = \mp j_y(x, y)$ and $j_z(\pm x, \mp y) = j_z(x, y)$. In the derivations presented below we will extensively use these symmetries.

SOLUTION FOR HALL RECONNECTION

Now let us list four assumptions that we make in this study. First, we assume that the plasma flow is incompressible inside the reconnection layer, $\rho = \text{constant}$. Second, we assume that the electrical resistivity η is constant and very small, so that the Lundquist number is very large. Third, we assume that the reconnection process is slow and quasi-stationary, so that we can neglect all time-derivatives $\partial/\partial t$ in Eqs. (1)–(2) and below. This assumption is satisfied if the reconnection rate is slow, $E_z \ll V_A B_m$, and there are no plasma instabilities in the reconnection layer. Fourth, we assume that the electron and ion pressure tensors are isotropic, so that the pressure tensors in Eqs. (1) and (2) are scalars.

Using Ampere’s law and neglecting the displacement current, we find the x - and y -components of the current to be $j_x = \partial_y B_z$ and $j_y = -\partial_x B_z$. Here and below we use convenient notations $\partial_x \equiv \partial/\partial x$, $\partial_y \equiv \partial/\partial y$, $\partial_{yy}^2 \equiv \partial^2/\partial y^2$, $\partial_{xyy}^3 \equiv \partial^3/\partial x \partial y^2$, and etc. The z -component of the current at the reconnection layer central point O is

$$j_o \equiv (j_z)_o = (\partial_x B_y - \partial_y B_x)_o \approx B_m/\delta, \quad (3)$$

where we use estimates $(\partial_y B_x)_o \ll (\partial_x B_y)_o$ and $(\partial_x B_y)_o \approx B_m/\delta$ at point O .

Next, neglecting the time derivative in Eq. (2), the equation for acceleration of plasma along the reconnection layer, in the y -direction, is $\rho(\mathbf{V} \cdot \nabla)V_y = -\partial_y P +$

$j_z B_x - j_x B_z$. We calculate the first order partial derivative $\partial/\partial y$ of this equation at point O and obtain

$$\begin{aligned} \rho(\partial_y V_y)_o^2 &= -(\partial_{yy}^2 P)_o + j_o(\partial_y B_x)_o \\ &\approx -B_m(\partial_{yy}^2 B_y)_m + j_o(\partial_y B_x)_o, \\ &= 2B_m^2/L^2 + j_o(\partial_y B_x)_o. \end{aligned} \quad (4)$$

Here, we used the fact that the pressure term is $(\partial_{yy}^2 P)_o \approx (\partial_{yy}^2 B_y^2/2)_m - (\partial_{yy}^2 B_z^2/2)_o = B_m(\partial_{yy}^2 B_y)_m < 0$. Thus, the drop of pressure P along the layer is equal to the magnetic pressure drop of the parallel field component outside the layer. This result follows from the force balance condition for the plasma across the reconnection layer (in analogy with the Sweet-Parker derivations for slowly inflowing plasma), and its rigorous proof can be found in [5]. The last expression in Eq. (4) is obtained by defining the magnetic field external scale as

$$L^2 \equiv -2B_m/(\partial_{yy}^2 B_y)_m. \quad (5)$$

This is the scale of magnetic field just outside the reconnection electron layer (at point M) and can be interpreted as the length of the layer. The $(\partial_y V_y)_o$ derivative on the left-hand-side of Eq. (4) can be estimated from plasma incompressibility condition at the O -point,

$$(\partial_y V_y)_o = -(\partial_x V_x)_o \approx V_{in}/\delta, \quad (6)$$

where we use an estimate $(\partial_x V_x)_o \approx -V_{in}/\delta$.

Next, the Faraday’s law $\nabla \times \mathbf{E} = -\partial \mathbf{B}/\partial t$ for the x - and y -components of a quasi-stationary magnetic field in two dimensions is $\partial E_z/\partial y = -\partial B_x/\partial t \approx 0$ and $\partial E_z/\partial x = \partial B_y/\partial t \approx 0$. Therefore, the electric field z -component E_z is constant in space, and from generalized Ohm’s law (1) we obtain

$$\begin{aligned} \text{constant in space} \approx E_z &= -V_x B_y + V_y B_x + \eta j_z \\ &+ (m_p/\rho e)(j_x B_y - j_y B_x). \end{aligned} \quad (7)$$

Now, we use Eq. (7) to calculate E_z at points O and M (see Fig. 1). At point O we have $E_z = \eta j_o$. At point M we have $E_z = V_{in} B_m + \eta(j_z)_m + (m_p/\rho e)B_m(j_x)_m \approx V_{in} B_m + \eta(j_z)_m + (m_p/\rho e)B_m(\partial_{xy}^2 B_z)_o \delta$, where we use an estimate $(j_x)_m \approx (\partial_x j_x)_o \delta = (\partial_{xy}^2 B_z)_o \delta$. Equating these two expressions for E_z at points O and M and neglecting the resistive term outside the reconnection layer at point M , $\eta(j_z)_m \approx \eta B_m/L \ll \eta j_o$, we obtain

$$\eta j_o \approx V_{in} B_m + (m_p/\rho e)B_m(\partial_{xy}^2 B_z)_o \delta. \quad (8)$$

Next, we calculate the second order partial derivative $\partial^2/\partial y^2$ of Eq. (7) at point O . We have

$$\begin{aligned} 0 &\approx 2(\partial_y V_y)_o(\partial_y B_x)_o + \eta(\partial_{yy}^2 j_z)_o \\ &- 2(m_p/\rho e)(\partial_y j_y)_o(\partial_y B_x)_o \\ &\approx 2(\partial_y V_y)_o(\partial_y B_x)_o - \eta(2j_o/L^2) \\ &+ 2(m_p/\rho e)(\partial_{xy}^2 B_z)_o(\partial_y B_x)_o. \end{aligned} \quad (9)$$

Here, to obtain the final expression, we use the fact that the y-scale of the current j_z , to a factor of order unity, is about the same as the y-scale of the outside magnetic field, $j_o^{-1}(\partial_{yy}^2 j_z)_o \approx B_m^{-1}(\partial_{yy}^2 B_y)_m = -2/L^2$. This result can be understood by taking the $\partial^2/\partial y^2$ partial derivative of the Ampere's law equation $j_o \approx B_m/\delta$, see Eq. (3), while keeping δ constant because the partial derivative in y is to be taken at constant $x = \delta$ (for details see [5]).

Next, we use the z-component of the Faraday's law. We have $0 \approx -\partial B_z/\partial t = \partial_x E_y - \partial_y E_x$. We calculate the $\partial^2/\partial x \partial y$ partial derivative of this equation at point O and use Ohm's law (1) for E_x and E_y . After tedious but straightforward derivations, we obtain

$$\begin{aligned} 0 &\approx -\eta [(\partial_{xyxx}^4 B_z)_o + (\partial_{xyyy}^4 B_z)_o] \\ &\quad - [(\partial_y B_x)_o (\partial_{xx}^2 V_z)_o + (\partial_x B_y)_o (\partial_{yy}^2 V_z)_o] \\ &\quad + (m_p/\rho e) [(\partial_y B_x)_o (\partial_{xx}^2 j_z)_o + (\partial_x B_y)_o (\partial_{yy}^2 j_z)_o] \\ &\approx 2\eta (\partial_{xy}^2 B_z)_o / \delta^2 \\ &\quad - 2(m_p/\rho e) [(j_o/\delta^2)(\partial_y B_x)_o + j_o^2/L^2]. \end{aligned} \quad (10)$$

Here, to derive the final expression, we use $(\partial_{xyxx}^4 B_z)_o \approx -2(\partial_{xy}^2 B_z)_o/\delta^2$, $(\partial_{xyyy}^4 B_z)_o \ll (\partial_{xyxx}^4 B_z)_o$, $(\partial_{xx}^2 j_z)_o \approx -2j_o/\delta^2$, $(\partial_{yy}^2 j_z)_o \approx -2j_o/L^2$ and $(\partial_x B_y)_o \approx j_o$. We also use formula $(\partial_y B_x)_o (\partial_{xx}^2 V_z)_o + (\partial_x B_y)_o (\partial_{yy}^2 V_z)_o \equiv 0$. To prove it, let us consider the z-component of plasma motion equation (2), which is $\rho V_x(\partial_x V_z) + \rho V_y(\partial_y V_z) = j_x B_y - j_y B_x$. We calculate the $\partial^2/\partial x^2$ and $\partial^2/\partial y^2$ derivatives of this equation at point O and obtain $2\rho(\partial_x V_x)_o (\partial_{xx}^2 V_z)_o = 2(\partial_x j_x)_o (\partial_x B_y)_o$ and $2\rho(\partial_y V_y)_o (\partial_{yy}^2 V_z)_o = -2(\partial_y j_y)_o (\partial_y B_x)_o$. Thus, we have $(\partial_{xx}^2 V_z)_o = -(\partial_{xy}^2 B_z)_o (\partial_x B_y)_o / \rho (\partial_y V_y)_o < 0$, $(\partial_{yy}^2 V_z)_o = (\partial_{xy}^2 B_z)_o (\partial_y B_x)_o / \rho (\partial_x V_x)_o > 0$ and $(\partial_y B_x)_o (\partial_{xx}^2 V_z)_o + (\partial_x B_y)_o (\partial_{yy}^2 V_z)_o \equiv 0$.

Now, we have six equations (3), (4), (6), (8), (9) and (10), and we have six unknowns: j_o , δ , V_{in} , $(\partial_y V_y)_o$, $(\partial_y B_x)_o$ and $(\partial_{xy}^2 B_z)_o$. Thus, we can solve for all unknown quantities. For convenience of presentation, we express the solution in terms of the Alfvén velocity $V_A = B_m/\sqrt{\rho}$, the ion inertial length $d_i = m_i/e\sqrt{\rho}$ and the Lundquist number $S = LV_A/\eta$. The solution is

$$j_o \approx \frac{B_m}{L} \left(S\sqrt{3} + 2S^2 d_i^2 / L^2 \right)^{1/2}, \quad (11)$$

$$\delta \approx L \left(S\sqrt{3} + 2S^2 d_i^2 / L^2 \right)^{-1/2}, \quad (12)$$

$$V_{in} \approx \sqrt{3} V_A \left(S\sqrt{3} + 2S^2 d_i^2 / L^2 \right)^{-1/2}, \quad (13)$$

$$(\partial_y V_y)_o \approx \sqrt{3} V_A / L, \quad (14)$$

$$(\partial_y B_x)_o \approx \frac{B_m}{L} \left(S\sqrt{3} + 2S^2 d_i^2 / L^2 \right)^{-1/2}, \quad (15)$$

$$(\partial_{xy} B_z)_o \approx 2S d_i B_m / L^3, \quad (16)$$

$$E_z \approx \eta j_o \approx V_A B_m \left(S^{-1} \sqrt{3} + 2d_i^2 / L^2 \right)^{1/2}. \quad (17)$$

The last equation gives the reconnection rate E_z . In the limit $S \gg 1$ and $d_i \ll L$ the reconnection rate

is slow, $E_z \ll V_A B_m$, and our assumption of a quasi-stationary reconnection process is self-consistent. Equation (14) implies that the ions are accelerated up to approximately Alfvén velocity V_A along the reconnection layer of length L . At the same time, the rate of electron acceleration along the layer at point O is $(\partial_y V_y^e)_o = (\partial_y V_y)_o - (m_i/\rho e)(\partial_y j_y)_o = (\partial_y V_y)_o + (V_A d_i/B_m)(\partial_{xy} B_z)_o \approx (V_A/L)(\sqrt{3} + 2S d_i^2/L^2)$, where $\mathbf{V}^e$ denotes the electron velocity.

The ion layer thickness 2Δ can be estimated as follows. In the upstream region outside the ion layer at $x = \Delta$ ideal single-fluid MHD applies. Therefore, at $x = \Delta$ and $y = 0$ the resistive and Hall terms in Eq. (7) can be neglected and $E_z \approx V_R B_m$, where V_R is the plasma inflow velocity outside the ion layer. Velocity $V_R \approx E_z/B_m$ is called the reconnection velocity. It can also be estimated as $V_R \approx (\partial_y V_y)_o \Delta$. Thus,

$$\Delta \approx \frac{E_z}{(\partial_y V_y)_o B_m} \approx \frac{L}{\sqrt{3}} \left(S^{-1} \sqrt{3} + 2d_i^2 / L^2 \right)^{1/2}. \quad (18)$$

We discuss the solution (11)-(18) in the next section. Now, let us make an important remark. Our analytical derivations involve an approximate solution of the Hall-MHD equations in the infinitesimal neighborhood of line OM across the reconnection electron layer (see Fig. 1). All physical quantities, j_o , δ , V_{in} , $(\partial_y V_y)_o$, $(\partial_y B_x)_o$, $(\partial_{xy} B_z)_o$, B_m and L , are defined either at point O (the layer center) or at point M (the upstream region). In other words, all our derivations involve only the upstream region and the layer center, and we do not need to consider the downstream region for estimation of the reconnection rate. This “local” equations approach was first developed in [5] for single-fluid MHD reconnection with anomalous electrical resistivity, and this approach works for Hall-MHD reconnection as well. Note however, that we define the field scale L by Eq. (5), and its exact value, as well as the value of field B_m in the upstream region, depend on the “global” solution of the Hall-MHD equations outside the reconnection layer. Both L and B_m enter our model as parameters. Determination of their values requires numerical simulations of the global field configuration and is not considered here.

DISCUSSION

When $d_i \ll L/\sqrt{S} = \delta_{SP}$ (δ_{SP} is the Sweet-Parker layer thickness), the solution (11)-(18) reduces to the Sweet-Parker solution: $j_o \approx \sqrt{S} B_m/L$, $\delta \approx \Delta \approx L/\sqrt{S} = \delta_{SP}$, $V_{in} \approx V_A/\sqrt{S}$, $(\partial_y V_y)_o \approx V_A/L$, $(\partial_y B_x)_o \approx B_m/L\sqrt{S}$, $E_z \approx V_A B_m/\sqrt{S}$ and $(\partial_y V_y^e)_o \approx (\partial_y V_y)_o \approx V_A/L$.

In the opposite limit, when $d_i \gg L/\sqrt{S} = \delta_{SP}$ and

reconnection is in a collisionless Hall regime, we have

$$j_o \approx S d_i B_m / L^2 \gg \sqrt{S} B_m / L, \quad (19)$$

$$\delta \approx L^2 / S d_i \ll L / \sqrt{S} = \delta_{SP}, \quad (20)$$

$$\Delta \approx d_i \gg L / \sqrt{S} = \delta_{SP}, \quad (21)$$

$$V_{in} \approx V_A L / S d_i \ll V_A / \sqrt{S}, \quad (22)$$

$$(\partial_y V_y)_o \approx V_A / L, \quad (23)$$

$$(\partial_y B_x)_o \approx B_m / S d_i, \quad (24)$$

$$(\partial_{xy} B_z)_o \approx 2 S d_i B_m / L^3, \quad (25)$$

$$E_z \approx (d_i / L) V_A B_m \gg V_A B_m / \sqrt{S}. \quad (26)$$

The electron acceleration rate along the reconnection layer at O-point is $(\partial_y V_y^e)_o \approx S d_i^2 V_A / L^3 \gg (\partial_y V_y)_o$. Fast electron outflow along the layer creates the quadrupole field B_z [18]. From Eq. (26) we find that the rate of collisionless Hall reconnection, $E_z = (d_i / L) V_A B_m$, is independent of the electrical resistivity η [19]. The reconnection velocity is $V_R \approx E_z / B_m \approx (d_i / L) V_A$. From Eq. (21) we find $\Delta \approx d_i$ for the ion layer thickness, which is in agreement with experiment [13].

In it noteworthy that in the absence of collisions, when $\eta \rightarrow 0$, it is an anisotropic electron pressure that balances E_z field at point O. In this case electrons are accelerated by E_z field during time $\sim L / V_{eT}$, while they are unmagnetized and are traveling with thermal speed V_{eT} inside the electron layer of length L [3, 20]. As a result, the effective resistivity becomes $\eta_{\text{eff}} \approx d_e^2 V_{eT} / L$, where $d_e = \sqrt{m_i m_e} / e \sqrt{\rho}$ is the electron inertial length (m_e is the electron mass). Thus, pressure anisotropy and electron inertia become important (they will be considered elsewhere).

In the end of this paper, let us briefly discuss possible mechanisms of fast reconnection, which is independent of the macroscopic size of the reconnecting system. First, note that the collisionless Hall reconnection rate $E_z = (d_i / L) V_A B_m$ is high when the reconnection electron layer length L is microscopically small and comparable to d_i . Although the value of L cannot be determined in our model, numerical simulations find that L can indeed be much smaller than the macroscopic system size [7, 8, 14, 15, 16, 17]. For example, L can be as small as $\approx 10 d_i$ during quasi-stationary collisionless reconnection, resulting in a very fast reconnection rate $E_z \approx 0.1 V_A B_m$ [8, 16, 17].

Another possible mechanism of fast reconnection can result from the dependence of the reconnection rate on the density ρ and temperature T of the plasma. We have $\eta \propto T^{-3/2}$ [10], $V_A \propto \rho^{-1/2}$, $S \propto \rho^{-1/2} T^{3/2}$, $d_i^2 \propto \rho^{-1}$. Therefore, $d_i / \delta_{SP} \propto (T / \rho)^{3/4}$, and the collisionless Hall reconnection rate is $E_z \propto \rho^{-1}$. Thus, even if initially $L \gg d_i$, as reconnection proceeds, the plasma is heated up by Joule heating, the plasma temperature rises, the plasma density drops, and the reconnection becomes more and more collisionless and faster and faster.

This run-away reconnection process can possibly operate in solar corona and Earth's magnetosphere. The dependence $E_z \propto \rho^{-1}$ also supports a model of self-regulation heating in solar corona [21].

I am especially grateful to Russell Kulsrud for many very helpful discussions and for pointing out to me the importance of electron pressure anisotropy. I would also like to thank Ellen Zweibel, Fausto Cattaneo, Masaaki Yamada, Boon Chye (BC) Low, Eugene Parker, Alex Obabko, Dmitri Uzdensky, Hantao Ji, Viacheslav Titov, Amitava Bhattacharjee and the anonymous referee for their interest in this work, discussions and for useful comments. This work was supported by the NSF Center for Magnetic Self-Organization (CMSO) in Laboratory and Astrophysical Plasmas at the University of Chicago.

A note added after publication: After the publication of his paper, the author has become aware that Simakov and Chacon (2008) have independently obtained a Hall reconnection rate formula, which is the same as Eq. (17) up to numerical factors of order unity [22]. Although the final result is basically the same, the two derivations are significantly different. The author has used a rigorous local analysis, in which the Hall-MHD equations are solved only in the upstream region and in the center of the reconnection layer. By contrast, Simakov and Chacon (2008) have used a different approach that also considers the downstream region. In particular, they have assumed that the thickness of the ion layer is given by $\max\{d_i, \delta\}$, and obtained their reconnection rate formula as an approximate interpolation between the rates in the collisional and collisionless regimes. There are also minor differences in the problem formulation; that of Simakov and Chacon (2008) includes electron viscosity, which is neglected by the author, and neglects electron pressure, which is included by the author. Expression $(d_i / L) V_A$ for the reconnection velocity in the collisionless regime was obtained earlier by Stanley W. H. Cowley (1985) [19].
